Colorado State University is an equal opportunity/affirmative action institution and complies with all Federal and Colorado State laws, regulations, and executive orders regarding affirmative action requirements in all programs. The Office of Equal Opportunity is located in 101 Student Services. In order to assist Colorado State University in meeting its affirmative action responsibilities, ethnic minorities, women, and other protected class members are encouraged to apply and to so identify themselves.

INTRODUCTION

Biosolids recycling on dryland winter wheat (*Triticum aestivum*, L.) can supply a reliable, slow-release source of nitrogen (N) and organic carbon (Barbarick et al., 1992). Barbarick and Ippolito (2000, 2007) found that continuous application of biosolids from the Littleton/Englewood, CO wastewater treatment facility to dryland winter wheat-fallow rotation provides 16 to 18 lbs N per dry ton. This research involved tilling the biosolids into the top 8 inches of soil. A new question related to soil management in a biosolids beneficial-use program is: How much N would be available if the biosolids were surface-applied in a no-till dryland agroecosystem with winter wheat-fallow (WF) and winter wheat-corn (*Zea mays*, L.)-fallow (WCF) crop rotations?

Our objective was to compare agronomic rates of commercial N fertilizer to an equivalent rate of biosolids in combination with WF and WCF crop rotations. Our hypotheses were that biosolids addition, compared to N fertilizer, will:

1. Produce similar crop yields;
2. Not differ in grain P, Zn, and Cu levels (Ippolito and Barbarick, 2000) or soil P, Zn, and Cu AB-DTPA extractable concentrations, a measure of plant availability (Barbarick and Workman, 1987); and
3. Not affect soil salinity (electrical conductivity of saturated soil-paste extract, EC) or soil accumulation of nitrate-N ($\text{NO}_3\text{-N}$).

MATERIALS AND METHODS

In 1999, we established our research on land owned by the Cities of Littleton and Englewood (L/E) in eastern Adams County, approximately 28 miles east of Byers, CO. The Linnebur family manages the farming operations for L/E. Soils belong to the Adena-Colby association where the Adena soil is classified as an Ustollic Paleargid and Colby is classified as an Ustic Torriorthent. No-till management is used in conjunction with crop rotations of WF and WCF. We originally also used a wheat-wheat-corn-sunflower (*Helianthus annuus*, L.)-fallow rotation. After the 2004 growing season, we abandoned this rotation because of persistent droughty conditions that restricted sunflower production.

We installed a Campbell Scientific weather station at the site in April 2000; Tables 1 and 2 present mean temperature and precipitation data, and growing season precipitation, respectively.

With biosolids application in August 1999, we initiated the study. Planting sequences are given in Table 3. We used two replications of each rotation (20 plots total) and we completely randomized each replicated block. Each phase of each rotation was present every year. Each plot was 100 feet wide by approximately 0.5 mile

(2640 feet) long. The width was split so that one 50-foot wide section received commercial N fertilizer applied with the seed and sidedressed after plant establishment (Table 3), and the second 50-foot wide section received biosolids applied by L/E with a manure spreader. We randomly selected which strip in each rotation received N fertilizer or biosolids. Characteristics of the L/E biosolids are provided in Table 4. We based the N fertilizer and biosolids applications on soil test recommendations determined on each plot before planting each crop. The Cities of L/E completed biosolids application for the summer crops in March 2000, 2001, 2002, 2003, 2004, and 2005. We planted the first corn crop in May 2000. We also established wheat rotations in September 2000, 2001, 2002, and 2003, corn rotations in May 2001, 2002, 2003, and 2004, and sunflower plantings in June 2001, 2002, and 2003. Soil moisture was inadequate in June 2004 to plant sunflowers (see Table 1).

We completed wheat harvests in July 2000, 2001, 2002, 2003, 2004, 2005, and 2007 and corn and sunflowers in October 2000 and 2001, sunflowers in December 2003, and corn in 2004, 2006, and 2007. We experienced corn and sunflower crop failures in 2002, a corn crop failure in 2003 and 2005, and a wheat-crop failure in 2006 due to lack and proper timing of precipitation (Table 1). For each harvest, we cut grain from four areas of 5 feet by approximately 100 feet within each subplot. We determined the yield for each area and then took a subsample from each cutting for subsequent grain protein or N, P, Zn, and Cu analyses (Huang and Schulte, 1985).

Following each harvest, we collected soil samples using a Giddings hydraulic probe. For AB-DTPA extractable Cu, P, and Zn (Barbarick and Workman, 1987) and EC (Rhoades, 1996) and pH (Thomas, 1996), we sampled to one foot and separated the samples into 0-2, 2-4, 4-8, and 8-12 inch depth increments. For soil NO₃-N (Mulvaney, 1996) analyses, we sampled to 6 feet and separated the samples into 0-2, 2-4, 4-8, 8-12, 12-24, 24-36, 36-48, 48-60, and 60-72 inch depth increments.

For the wheat rotations, the experimental design was a split-plot design where type of rotation was the main plot and type of nutrient addition (commercial N fertilizer versus L/E biosolids) was the subplot. For crop yields and soil-sample analyses, main plot effects, subplot effects, and interactions were tested for significance using least significant difference (LSD) at the 0.10 probability level. Since we only had one corn rotation, we could only compare the commercial N versus L/E biosolids using a “t” test at the 0.10 probability level.

RESULTS AND DISCUSSION

Precipitation Data

Table 1 presents the monthly precipitation records from the time we established the weather station at the Byers research site. The plots received more than 11 inches of total annual rainfall in 2000, 2001, and 2007, only 5 inches in 2002, about 12 inches in 2003, 10 inches in 2004 and 2005, 9 inches in 2006. The critical precipitation months for corn are July and August (Nielsen et al., 1996). The Byers site received 6.0, 3.8, 1.3, 2.6, 2.5, 3.5, 4.5, and 5.4 inches of precipitation in July and August 2000, 2001, 2002, 2003, 2004, 2005, 2006, and 2007, respectively.

2007 Crop Grain Data

As shown in Figure 1, the WF rotation produced significantly larger wheat yields than the WCF rotation. Neither rotation nor nutrient source affected the grain protein, P, or Cu concentrations (Figures 2, 3, and 5). The biosolids treatment in the WCF rotation produced the highest wheat-grain Zn (Figure 4).

Biosolids significantly increased the corn-grain P concentration relative to the N fertilizer treatment but did not affect the grain yields or Cu or Zn levels (Table 5).

2007 Soil Data

The AB-DTPA-extractable P concentration (Figure 6) in the 0-2-inch depth is considered medium or high according to the Colorado P Index Risk Assessment (Sharkoff et al., 2003). Overall, this site would most likely have a “medium” risk assessment in terms of the potential for off-site P movement. Interpreted, biosolids land application can still follow crop N requirements.

The AB-DTPA-extractable P, Zn, and Cu concentrations in the top 2 inches of soil were significantly affected by rotation, treatment, and the interaction between rotation and treatment. For all three nutrients, the higher concentrations were found in the WCF rotation that received biosolids.

The salinity level (EC; Figure 9) showed inconsistent trends with rotation and nutrient source. Soil pH (Figure 10) was higher in the WCF rotation in the top 8 inches of soil.

Only the 2-4-inch soil depth showed an increase in NO₃-N in the biosolids plots (Figure 11). The residual NO₃-N in the top 36 inches also indicates that future biosolids

and fertilizer applications to both wheat and corn should be ceased until the soil NO₃-N levels are reduced to below 15 mg kg⁻¹ (ppm). Nitrogen additions to winter wheat are needed when soil NO₃-N concentrations are less than 15 mg kg⁻¹ (ppm) in the top foot (Davis et al., 2005). Nitrogen additions to dryland corn are needed when soil NO₃-N concentrations are less than 12 mg kg⁻¹ (ppm) in the top foot (Mortvedt et al., 1996).

CONCLUSIONS

Relative to our hypotheses listed on page 3, we have found the following trends:

1. In the wheat plots, we observed similar concentrations of P, Zn, and Cu in wheat grain and surface-soil levels following biosolids or N fertilizer application. We found no differences in soil NO₃-N concentrations (except at 2-4 inches) at depths to 6 feet.
2. We found that biosolids application did not provide consistent effects on soil salinity (EC) in the wheat plots as compared to N fertilizer applications.
3. Previous biosolids and N fertilizer applications, based on soil test N and crop N requirements, have caused an accumulation of NO₃-N in the soil profile. Therefore, near-future biosolids and N fertilizer applications will be ceased until soil NO₃-N is reduced by wheat and corn removal.

Figure 1. Wheat grain yields for 2007 dryland-wheat-rotation harvests comparing Littleton/Englewood biosolids to commercial fertilizer. In the statistical summary, $LSD_{0.10}$ represents the least significant difference at the 10% probability level and NS indicates non-significant differences. (WF = wheat-fallow and WCF = wheat-corn-fallow rotations).

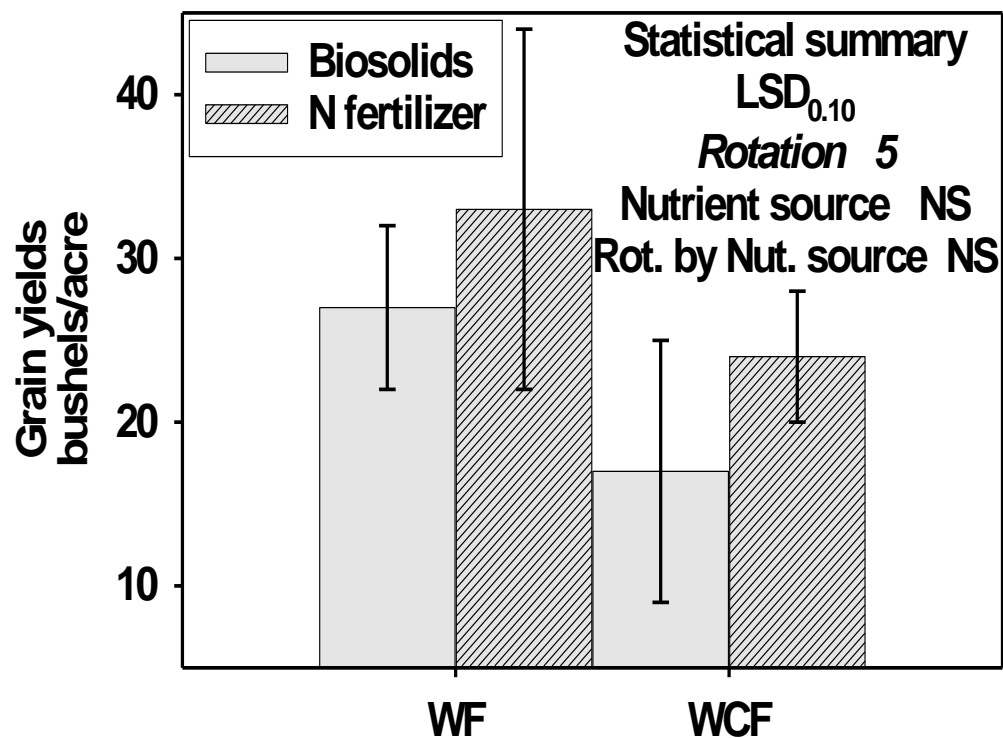

Figure 2. Wheat grain protein concentrations for 2007 dryland-wheat-rotation harvests comparing Littleton/Englewood biosolids to commercial fertilizer. In the statistical summary, $LSD_{0.10}$ represents the least significant difference at the 10% probability level and NS indicates non-significant differences. (WF = wheat-fallow and WCF = wheat-corn-fallow rotations).

Figure 3. Wheat grain P concentrations for 2007 dryland-wheat-rotation harvests comparing Littleton/Englewood biosolids to commercial fertilizer. In the statistical summary, $LSD_{0.10}$ represents the least significant difference at the 10% probability level and NS indicates non-significant differences. (WF = wheat-fallow and WCF = wheat-corn-fallow rotations).

Figure 4. Wheat grain Zn concentrations for 2007 dryland-wheat-rotation harvests comparing Littleton/Englewood biosolids to commercial fertilizer. In the statistical summary, $LSD_{0.10}$ represents the least significant difference at the 10% probability level and NS indicates non-significant differences. (WF = wheat-fallow and WCF = wheat-corn-fallow rotations).

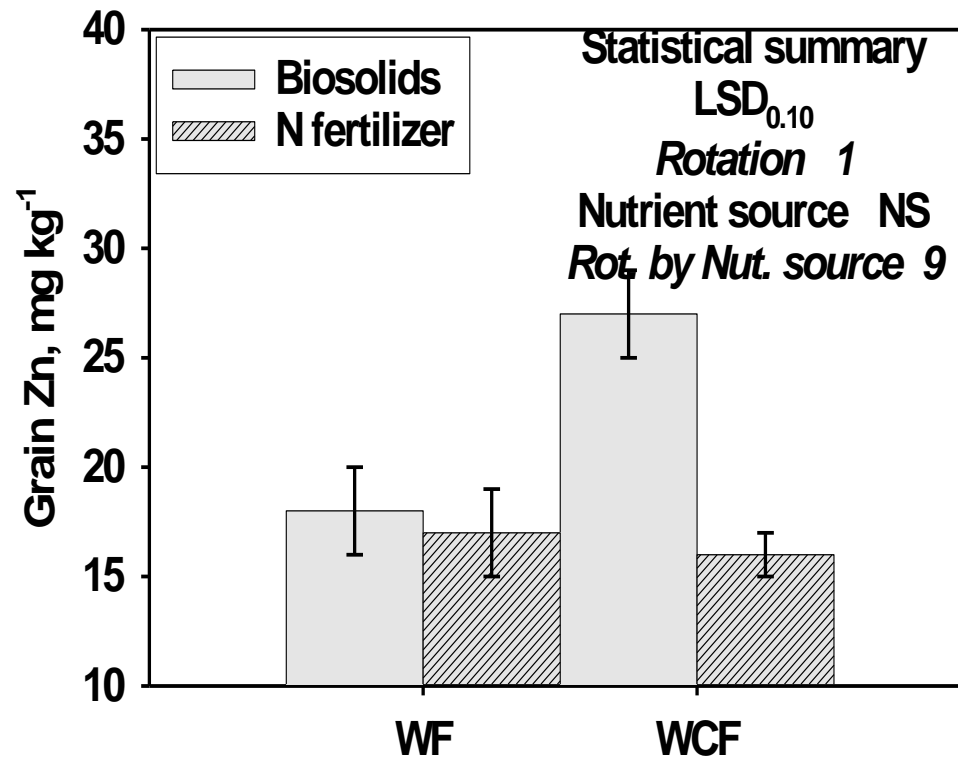

Figure 5. Wheat grain Cu concentrations for 2007 dryland-wheat-rotation harvests comparing Littleton/Englewood biosolids to commercial fertilizer. In the statistical summary, $LSD_{0.10}$ represents the least significant difference at the 10% probability level and NS indicates non-significant differences. (WF = wheat-fallow and WCF = wheat-corn-fallow rotations).

Figure 6. Soil AB-DTPA-extractable P concentration following 2007 dryland-wheat-rotation harvests comparing Littleton/Englewood biosolids to commercial N fertilizer. In the statistical summary, $LSD_{0.10}$ represents the least significant difference at the 0.10 probability level and NS indicates non-significant differences.

Figure 7. Soil AB-DTPA-extractable Zn concentration following 2007 dryland-wheat-rotation harvests comparing Littleton/Englewood biosolids to commercial N fertilizer. In the statistical summary, $LSD_{0.10}$ represents the least significant difference at the 0.10 probability level and NS indicates non-significant differences.

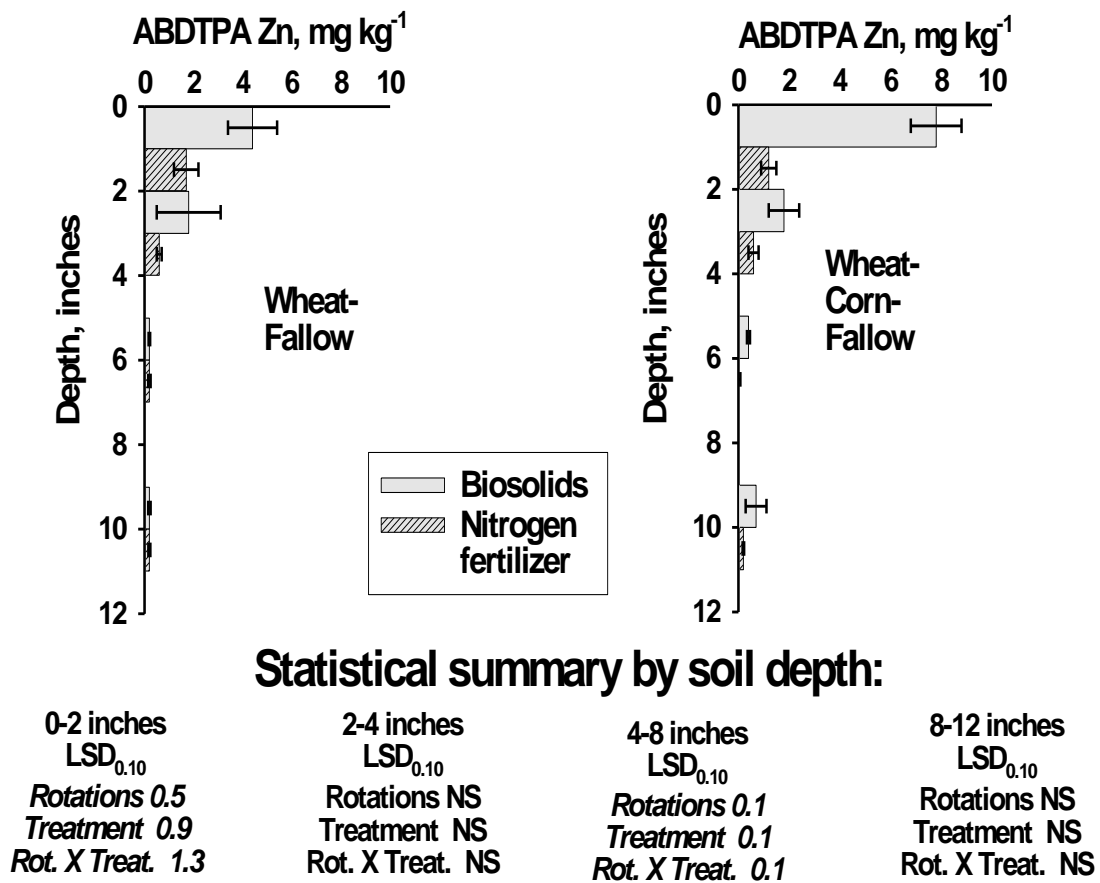

Figure 8. Soil AB-DTPA-extractable Cu concentration following 2007 dryland-wheat-rotation harvests comparing Littleton/Englewood biosolids to commercial N fertilizer. In the statistical summary, $LSD_{0.10}$ represents the least significant difference at the 0.10 probability level and NS indicates non-significant differences.

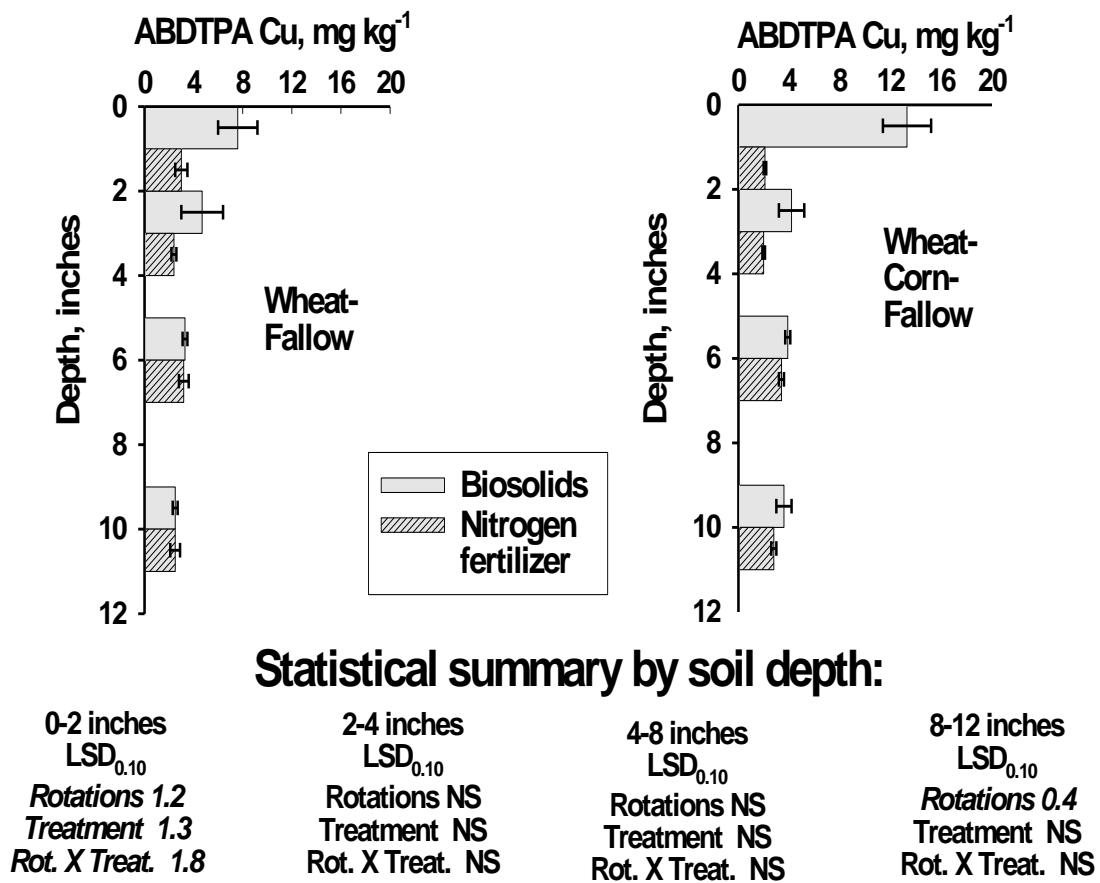

Figure 9. Soil saturated-paste electrical conductivity (EC) following 2007 dryland-wheat-rotation harvests comparing Littleton/Englewood biosolids to commercial N fertilizer. In the statistical summary, $LSD_{0.10}$ represents the least significant difference at the 0.10 probability level and NS indicates non-significant differences.

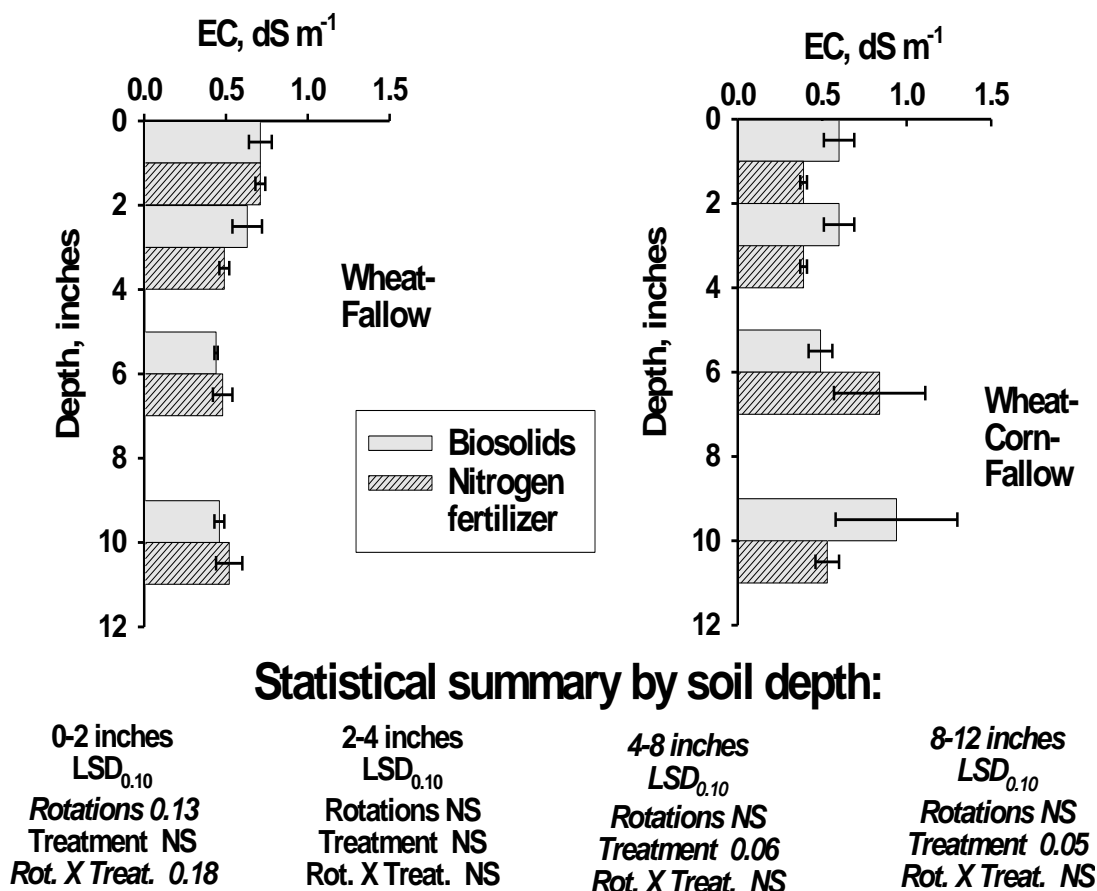

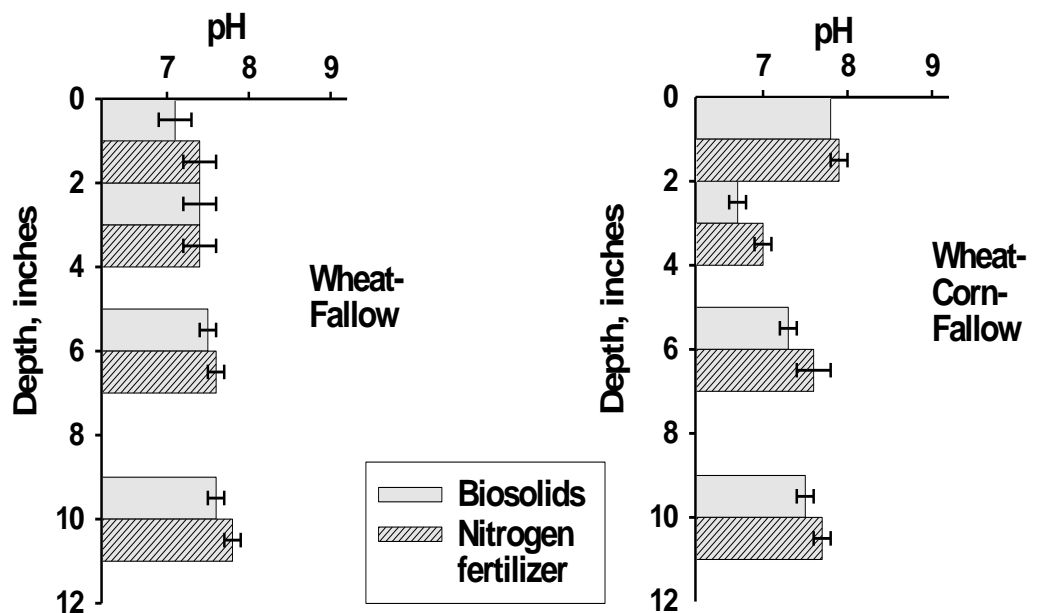

Figure 10. Soil saturated-paste pH following 2007 dryland-wheat-rotation harvests comparing Littleton/Englewood biosolids to commercial N fertilizer. In the statistical summary, $LSD_{0.10}$ represents the least significant difference at the 0.10 probability level and NS indicates non-significant differences.

Statistical summary by soil depth:

<p>0-2 inches $LSD_{0.10}$ <i>Rotations 0.3</i> Treatment NS Rot. X Treat. NS</p>	<p>2-4 inches $LSD_{0.10}$ <i>Rotations 0.44</i> Treatment NS Rot. X Treat. NS</p>	<p>4-8 inches $LSD_{0.10}$ <i>Rotations 0.2</i> Treatment NS Rot. X Treat. NS</p>	<p>8-12 inches $LSD_{0.10}$ Rotations NS Treatment 0.2 Rot. X Treat. NS</p>

Figure 11. Soil NO₃-N concentrations following 2007 dryland-wheat-rotation harvests comparing Littleton/Englewood biosolids to commercial N fertilizer. In the statistical summary, LSD_{0.10} represents the least significant difference at the 0.10 probability level and NS indicates non-significant differences.
